## SOFTWARE TOOLS FOR SOFTWARE MAINTENANCE

Software maintenance continues to be among the most critical issues facing all software development organizations. Developers are facing increasing demands for new software applications while at the same time having to devote sizable resources to maintaining existing applications. It seems that software development organizations will reach steady-state when all available resources are devoted to software maintenance. Increasing the productivity of software developers and increasing the quality of systems produced is certainly a high priority in development organizations; however, software maintenance productivity seems to be at least as important but not as eagerly addressed.

Software maintenance has been reported as containing 70-80% of the total software life cycle costs [FC1]. In the federal government software maintenance is reported to cost an estimated \$5 billion [FC2]. In a summary of 75 major companies, 53% of the total software related activities is in maintenance. In a survey conducted by IBM, over 80% of data processing resources are allocated to maintenance. Even a small increase in productivity in software maintenance will have a dramatic impact on overall data processing costs. *..(H F)*

There has been much written about software development workbenches, computer aided software engineering, etc. but most of these fail to address the unique needs of maintenance programmers.

The most important impediment to maintaining software is understanding what the existing software does. This is difficult because the maintenance programmer is usually forced to use the code itself as the best documentation of the program. The requirements documents, design documents, comments in the code, etc. are often not kept up-to-date and programmers cannot use this documentation with confidence.

As part of an effort by AIRMICS to explore maintenance problem areas in order to specify an integrated set of tools that should be included in a Maintenance Work Station, a survey of software maintenance tools was conducted by AIRMICS in conjunction with a similar effort by the Purdue/University of Florida Software Engineering Research Center.

There are a considerable number of software maintenance support tools available, however, there are relatively few (maybe none?) sets of integrated maintenance tools.

The tools reported on in this survey are categorized by operating environment and by 13 different maintenance support functions, by 10 different languages supported, and by the source of information.

The tools in both the SERC and AIRMICS surveys, Appendices A and B, respectively, are listed in alphabetical order by product name.

Several software tools can be employed to make systems more maintainable. These tools provide automated documentation in a standard format, revers engineering tools to work backwards toward the original requirements, code reformatters to make code easier to read and logic easier to follow, code restructurers to optimally reorganize source code making it more structured and modular, data-name standardizers to provide for consistent data references in the source code, and many tools for managers to use in the control of maintenance activities.

A possible grouping of such tools would be:

1. Change Justification ( as opposed to redesign):
  - a. cost-benefit analysis tool
  - b. cost estimating tool
  - c. requirements specification tool
2. Management tools:
  - a. automated progress and status reporting tool
  - b. configuration management tool
  - c. project budgeting, planning, scheduling, and control tool
3. Aids to understanding existing system:
  - a. data tracking and cross referencing tool
  - b. documentation tool
  - c. source code analyzer
4. Tools for testing changes:
  - a. editor that predicts impact of changes by working with data tracking tool

- b. test file generator
  - c. executive or job control language generator (emulating production)
  - d. test coverage monitor tool
  - e. source and file compare tool
5. Tools for use in preventive maintenance
- a. data name standardization tool
  - b. code restructuring tool
  - c. code reformatter tool
  - d. configuration management tool to maintain sets of tests for next change
  - e. metrics analyzer tool to measure effectiveness of maintenance group
6. Translation tool for use in preparing systems to run in more than one environment.

To consolidate/provide a concise view of these tools appropriate to ISEC we have provided below a listing by function supported of these tools that are useful with the COBOL and IBM environments. Additional information about the tools listed below can be found in the appendices. Tools are included for IBM Job Control Language (JCL) and those selected for the GSA Programmers Workbench are noted "(PWB)."

# A SURVEY OF SOFTWARE MAINTENANCE TOOLS THAT ENHANCE PROGRAM UNDERSTANDING

H.B. Holbrook and S.M. Theberge

Computer and Information Sciences Department  
University of Florida  
Gainesville, FL 32611

## ABSTRACT

This report summarizes the results of a recent survey of commercially available software tools which purport to aid in the task of program understanding. The effort was undertaken in connection with the SERC "Maintenance Assistant" Research Project at the University of Florida during the summer of 1987, and resulted in the identification of 116 tools. Most of the tools identified provide insight into the program structures and operations considered important for program comprehension.

## 1. INTRODUCTION

### 1.1. Background

In May of this year, the (SERC) "Maintenance Assistant" project was commissioned to study the problems of software maintenance and to investigate the concept of bringing together a combination of loosely integrated tools that could improve the productivity of maintenance programmers and increase the reliability of modified programs. One area of study has been that of "reverse software engineering" - the process of recovering "lost" or otherwise unavailable program requirements or design specifications that can aid in understanding the program and modifying it. Background work for study in this area included an examination of existing software tools which may aid in the task of program understanding. This survey is a result of that effort.

### 1.2. The Problem

"Performing maintenance, first and foremost, requires an understanding of the program - its functional objective, its internal structure, and its operational requirements." With that, Martin and McClure [1] summarize the relationship between software maintenance and program understanding. Unfortunately, the situation described by Fay and Holmes [2] below is familiar to many.

*You've been barraged with all of the facts: the original programmers are gone; the few comments that are in the code aren't necessarily correct (although they might be); and the small amount of documentation that exists (if any) is not necessarily correct or complete - it hasn't been updated for the last who-knows-how-many code updates.*

'Traditionally, programmers have had little automated support in dealing with such situations. Programs have been "analyzed" by trying to mimic computer functions with the aid of listings, paper clips, highlighters, and the maintainer's own limited mental capacity for dealing with masses of repetitive data.'

There now exist, however, tools that can provide users with relevant information on various aspects of a program (or system) in convenient forms. This report provides an overview of these tools.

### 1.3. Understanding Programs

As suggested by Brooks [3] and others, understanding a program is a process which involves reconstructing mappings from the programming domain to the problem domain. A programmer accomplishes this by generating a hierarchy of hypotheses about how a program meets a user's needs. From this perspective, understanding occurs when a programmer verifies (or adjusts) his hypotheses based on structures or operations found within the code. The classes of tools we have identified here support what Brooks calls "the verification process" of finding the operations and structures within a program that satisfy the hypotheses generated.

Another view of program understanding is offered by Letovsky and Soloway [4], and involves what are called "programming plans." These correspond roughly to Brooks' hypotheses. The understanding process here is associated with recognizing the plans in the existing code. Unfortunately, plans can be hard to recognize in the code if they are "delocalized," or spread through code that performs other functions. Many of the surveyed tools can be very useful in isolating delocalized plans.

### 1.4. Scope of Effort

Our research in reverse engineering is based, in part, on the premise that the only reasonably certain things a maintenance programmer will have to work with are the latest version of the source program in question and the system (hardware and operating system) on which it runs. Consequently, we have not investigated tools which require the availability of "external" information such as design specifications or other documentation, or which require adherence to a particular development methodology.

Furthermore, while we have tried to be thorough, the survey is by no means exhaustive and the tools we have listed are meant to be representative of the techniques under study.

## 2. METHODOLOGY

### 2.1. Sources

Tool information was obtained from several sources in our survey. One was product descriptions provided to us by vendors advertising in national software-oriented periodicals such as *Software Maintenance News* (SMN), an independent monthly which publishes articles dealing with all aspects of software maintenance [5].

Another source was a 1986 article by David Roman appearing in *Computer Decisions* which provided, in tabular form, a list of some 85 software maintenance tools along with their environments and functions [6]. The article also suggests a model for categorizing maintenance tools according to the functions provided.

A third source, the Office of Software Development and Information Technology of the US General Services Administration, publishes the *Software Aids and Tools Survey* which covers some 300 tools that apply to software engineering in general [7]. Information provided includes tool function, source language, cost, and producer.

Finally, the *JCP Software Directory* [8] consists of six volumes and some 18,000 software product and service descriptions for nearly all application areas. One volume is dedicated to systems software applications and covers many tools that deal with software maintenance. The directory provides source and environment information as well as a brief description of each tool.

### 2.2. Tool Categories

As we began our survey, it became obvious that we needed a reasonable way of classifying the functions of the tools identified. As a starting point, the US General Services Administration (GSA) categories as defined for their *Programmer's Workbench* project were utilized [6].

The *Programmer's Workbench* came about as the result of an effort to help federal information processing managers maintain their ever-growing mass of software. The categories identified functionally group tools the GSA felt were fundamental to maintenance programming. They are: test coverage monitors, translators, code reformatters, data standardization tools, cross referencers, documentation aids, file comparators, data manipulation tools, restructureurs, and code analyzers.

We considered seven of the ten GSA categories to be appropriate for our purposes, and added another. The categories we used are: test coverage monitors, code reformatters, cross referencers, documentation aids, restructureurs, source comparators, code analyzers, and execution monitors/debuggers. Descriptions of these categories are given in Section 4.

### 2.3. Storing the Data

Data from the survey have been stored in a Unify database and are available to SERC affiliates in various formats upon request. Tools are represented as separate records with the following fields (length in characters in parentheses): name (40), company (35), phone (15), function (25), environment (50), language (40), and source (12).

## 3. CATEGORIES AND REPRESENTATIVE TOOLS

In this section, the various categories of tools that aid in understanding computer programs are described. The basis for these categories is the GSA *Programmer's Workbench* project with modifications as explained in the previous section.

For each category, a brief description of the associated functions is provided. Examples of tools providing the specific functions described are given in parentheses. Following the category description, a summary list of representative tools is provided.

### 3.1. Code Analyzers

This group includes tools which statically analyze a program's control structure and data flow. By statically, we mean that the program itself is not executed and therefore its run-time behavior is not examined.

Code analysis tools vary greatly in the functions they perform. Most, however, fit within one of two categories: batch-oriented metrics generators, and interactive logic browsers.

The batch-oriented metrics generators produce measures which may be compared to predefined standards in order to assess the complexity of the software. In some cases, these tools may be used to determine the applicability of restructuring techniques (Pathvu, Superstructure).

Some of the interactive tools have been specifically designed to facilitate program understanding (Fastbol, Via/Insight). They provide the means for navigating through a program's logic or data flow by isolating specified classes of source statements (such as input, conditions, or particular control structures).

Other functions provided by code analyzers include the highlighting of "dead code" and the identification of other questionable coding practices (Basic Program Analyzer).

Table 1 lists tools that perform code analysis.

### 3.2. Documentation Aids

These tools generate graphical documentation which illustrates program logic at various levels of abstraction. Examples of output are flowcharts (Flowgen/F II, Flobol), calling hierarchies (Pathvu, Tree Diagrammer), and Warnier-Orr diagrams (Cobol-Warnier Generator).

Table 2 lists tools that generate program documentation.

### 3.3. Cross Referencers

These tools trace the use of data elements, named paragraphs, or procedures through a program. This is important to program understanding in that a function is very often recognized as a characteristic sequence of operations on a data structure. Thus, cross referencers may help in isolating

**Table 1**  
**Code Analysis Tools**

Tool Name	Language Supported
Basic Program Analyzer	Basic
C-Tracer	C
Cobol Structuring Facility	VS Cobol II

VAX Source Code Analyzer	Multiple languages
Via/Insight	Cobol
Wiseman	Basic

what Letovsky and Soloway call "delocalized plans" in which a particular function is spread throughout sections of seemingly unrelated code [4].

Object references are usually identified by source statement numbers. Associated with the statement numbers may be additional information such as the type of statement involved (move, assignment, conditional, etc.) or perhaps a copy of the statement itself.

Tool output is typically either a printed report or an on-line display. DCD II, for example, provides general data usage information within a Cobol data definition section of a source code listing. Optionally, it will produce an expanded cross reference listing that summarizes the types of operations associated with each data item.

Other tools operate from within an editor (Fastbol, Via/Insight) and provide on-line access to the information. Fastbol, for example, provides a cross-reference chart which displays how a data item is derived. From this display, the user may then go directly to the associated source code with a keystroke.

Some cross-reference tools allow the user to trace redefined data items (DCD II, Fastbol). This is especially important in dealing with Cobol group definitions or aliases. Some of the general file search tools (Dossier Browse, CICS/OLFU) may not provide this feature since they are language independent.

Table 3 lists tools that perform cross referencing.

### 3.4. Restructurers

Restructurers accept unstructured code as input and produce a structured program with the same functionality as output. The advertised advantage to structured code is that it enhances human readability and understanding by providing a hierarchical arrangement that allows for a quick grasp of the global as well as local structure of the program [9]. Moreover, the resultant code is of a consistent style - a situation which is not usual after numerous modifications by different programmers. There are, however, some questions about the usefulness of these tools. Interested readers may wish to review the October, November, and December 1980 issues of *Software Maintenance News* for

### 3.5. Reformatters

Reformatters are intelligent text editors which enhance program understanding by manipulating the pagination, spacing, and indentation of program source code. The use of a reformatters can result in a uniform coding style for the programs being maintained.

One of the important elements of reformatting is accurately depicting the scope of control statements, especially where there is complex nesting. This is done by key word alignment (If, else, while, begin, end, etc.) or by drawing lines to indicate scope (Source Print).

Some tools (CSA, Hawkeye) provide very useful features for reformatting Cobol code. These include provisions to enforce naming and level standards, to alphabetize working storage entries, and to sequence paragraph names.

**Table 4**

### 3.6. Execution Monitors/Debuggers

This group of tools allows the programmer to interactively monitor and manipulate the process of a program as it executes. In so doing, the maintenance programmer can directly examine the behavior of a program and the effects of various inputs.

Within this category, two basic functions are provided: tracing (Analyze, C-Tracer) and breakpointing (XPF/Cobol, JSCDebug). Tracing presents a history of a program's execution by building a record of various program statements as they are executed. The types of statements recorded can vary from paragraph names to variable names with their values. Traces are useful in identifying program paths for given conditions.

Breakpointing allows the user to halt an executing program at specified points (breakpoints) and examine or modify its data. This allows the user to interactively examine the effects of selected code segments and to explore the consequences of varying data values.

Table 6 lists tools that monitor program execution.

**Table 6**  
Execution Monitoring/Debugging Tools

Tool Name	Language Supported
Analyzer	Cobol
C-Tracer	C
CICS Interactive Cobol Debugging System	Cobol
FBUG/1000	Fortran
Interactive Debugging Monitor (IDM)	RPG
InterTest/CICS	Assembler
JSADebug-Assembler Debug	Assembler
JSCDebug-Cobol Debug	Cobol
QLODS (Quick Online Debugging System)	Cobol
Superbug	Assembler
Trace	Any
Tracer	Fortran Assembler
XDebug	Assembler
XPF/Assembler	Assembler
XPF/Cobol	Cobol

### 3.7. Test Coverage Monitors

Tools which monitor test case coverage keep track of which parts of a program are executed when a given set of test data is run. This involves executing an "instrumented" version of the program with the test data provided. Test monitors can enhance a programmer's understanding of a program by identifying the code segments associated with particular user-oriented functions.

Test coverage monitor reports can vary in form from static charts and tabular displays (Trailblazer) to on-line displays which are updated dynamically during symbolic debugging (XPF/Cobol).

Table 7 lists tools which monitor test case coverage.

**Table 7**  
Test Case Coverage Tools

Tool Name	Language Supported

XPF/Cobol	Cobol

### 3.8. Source Comparators

These tools are designed to help programmers quickly identify changes between program versions. This can be a significant aid in determining the rationale for previous undocumented maintenance. Table 8 lists tools that compare source listings.

**Table 8**  
Source Code Comparison Tools

Tool Name	Language Supported

## 4. CHARACTERISTICS OF THE TOOLS SURVEYED

In this section we provide a statistical summary of the tools identified with respect to function categories, source languages supported, and operating environments. Note that some tools are associated with more than one function category. In particular, 51 of the tools surveyed are associated with a single category, 36 are associated with two, and 29 are associated with three or more.

### 4.1. Number of Tools by Function and Language Supported

Table 9 shows the distribution of tools surveyed according to function and language. The abbreviations used are as follows:

Abbreviation	Function	Abbreviation	Language
SC	Source Code Comparators	CBL	Cobol
RF	Reformatters	FTN	Fortran
RS	Restructurers	CLG	C Language
CA	Code Analyzers	BSC	Basic
CR	Cross Referencers	PSC	Pascal
DA	Documentation Aids	NLS	No Language Specified
TM	Test Case Monitors	ANY	Any Language
DE	Execution Monitors/Debuggers	OTH	Other

### 4.2. Number of Tools by Function and Environment

Table 10 shows the distribution of tools surveyed according to function and operating environment.

**Table 9**  
**Number of Tools by Function and Language Supported**

Function	CBL	FTN	CLG	ASB	PSC	BSC	PLI	MDL2	RPG	ANY	NLS	OTH	Total

## Appendix: Maintenance Tool Database

The following is an alphabetical listing of tools contained in the SERC Maintenance Tool Database. Function categories (based loosely on those of the CSA) are abbreviated as follows:

- SC Source Code Comparitors - Identifies the differences between original and modified source listings.
- FC File Comparitors - Compare data files, even if organized differently.
- TR Translators - Convert programs from one language or version to another. Also may convert between operating systems.
- RF Reformatters - Reformat source code to make it easier to read and maintain.
- DS Data Standardization Tools - Locate and standardize data names.
- RS Restructurers - Convert unstructured programs into structured ones to improve readability and maintainability.
- CA Code Analyzers - Analyze the structure and logical flow of a program. Some also measure program complexity.
- CR Cross Referencers - Trace the use of data elements, named procedures or code paragraphs through a program. Also note what other programs a data element appears in.
- DA Documentation Aids - Automatically produce documentation for a program.
- DM Data Manipulation Tools - Allow programmers to extract data from a file, modify it, and put it into file structures. Useful for constructing test data.
- TM Test Case Monitors - Show which parts of a program are covered during execution.
- DE Execution Monitors/Debuggers - Allow programmers to interactively monitor and interact with an executing program.

The source languages that a tool supports are abbreviated as follows:

- CBL Cobol
- FTN Fortran
- CLG C Language
- BSC Basic
- PSC Pascal

The sources for tool information are abbreviated as follows:

- ICP *ICP Software Directory*, 55th Edition, 1986.
- CMT "Classifying Maintenance Tools," *Computer Decisions*, June 1986.
- FTS *Software Aids and Tool Survey*, Office of Software Development and Information Technology, 1986.

**APPENDIX B**

## Function Codes for Appendix B

Function Categories are abbreviated as follows:

CA Code Analyzer tool - Analyzes the structure and logical flow of a program. Some also measure program complexity.

CR Cross Reference tool - Traces the use of data elements, named procedures or code paragraphs through a program. Also notes appearance of data elements in source programs.

CG Code Generator tool - Generates source code from design specifications.

DA Documentation Aid tool - Automatically produces documentation for a program.

DE Execution Monitor/Debug tool - Allows programmers to interactively monitor and debug an executing program.

DM Data Manipulation tool - Allows programmers to extract data from a file, modify it, and re-insert it into file structures. Useful for constructing test data.

DS Data Standardization tool - Standardize data names between programs.

FC File Comparator tool - Compares data files even if they are organized differently.

MG Program Management/Change Control Tool - An aid to program management/change control

RF Reformatter tool - Reformats source code to make it easier to read.

RS Restructurer tool - Converts unstructured programs into structured ones to improve readability and maintainability.

SC Source Code Comparator tool - Identifies differences between original and modified source code.

TF Test File Generator tool - Prepares test data from information contained in source code.

TM Test Case Monitor tool - Shows which parts of a program are used during execution.

TR Translator tool - Converts programs from one language or version to another. Also may convert between operating systems.

### **Source Language Codes for Appendix B**

The source languages that a tool supports are abbreviated as follows:

**ASB** Assembler

**BSC** Basic

**CBL** Cobol

**CLG** "C" Language

**FTN** Fortran

**PSC** Pascal

**PL1** PL/1 Language

**CICS** Customer Information Control System (IBM only)

**RPG** Report Program Generator

**MDL2** Modula2
